Water Footprint for Different Industries-An Overview

Head of Civil Engineering Department,
Government Polytechnic Aurangabad

Abstract— Water footprint (WF) method is a compressive approach for evaluating direct and indirect water consumption in different sector, including the industrial, agricultural and domestic sector. In this review paper we are focusing on different case studies of water footprint for different industries. We are able to know about water consumption for various production process through this paper. The study reveal water risk, water scarcity and other water related challenges faced by human beings and helps in decision making for strategic actions based on the impacts on water resources that may be caused due to production process for different industry.

Keywords—Water footprint, Industry, water scarcity.

I. INTRODUCTION

Water is life. This statement refers to the worth of water for individuals and life on the planet. Water is essential for human beings, and thus access to clean water is considered a human right. Water crisis is a crucial issue because approximately 1.2 billion people face severe water scarcity [1]. The desirability of reducing our carbon footprint is generally recognised, but the related and equally urgent need to reduce our water footprint is often overlooked. Recent research has shown that about 4 % of the water footprint of humanity relates to water use at home [2]. To manage the global concern of freshwater scarcity, water footprint (WF) has emerged as an interactive tool for exploring the water use among the policy makers to encourage effective, justifiable and sustainable water use. The concept of WF, was initially introduced by Hoekstra [3] and consequently elaborated by Hoekstra and Chapagain [4]. WF is a consumption or pollution based indicator of water use allocated for producing a product, commodity or a service. Knowledge of how allocated surface and groundwater resources are consumed over the production process is highly valuable for effective planning, management and sustenance of water resources by policy makers [5] [6]. The WF of a product refers to the amount of water required for producing the product over the complete production chain. WF assessment is an analytical tool that can describe the relationship between human activities and water scarcity, and offers an innovative approach to integrated water resources management [7].

WF is divided into three components, blue WF, green WF and gray WF. Thus, blue WF refers to the water that is consumed and / or incorporated into the process of surface and underground water sources, which has the characteristic of not returning to the source of collection or returning in a long period of time [8]. The green WF represents the water stored in the form of moisture in the soil from precipitation and which is mainly consumed by the water requirements of agricultural crops [9] [10]. Finally, the gray WF refers to the quality of the

water resource. It represents the theoretical volume of water required by a water body to dilute pollutant load to the limit values allowed by environmental authorities [11] [12]. The WF can be measured and expressed per day, month or year depending on the level of information needed [13], and the WF of products is always expressed as water volume per product unit. Some of the examples are water volume per unit of mass (litre/kg or m³/t of products) if weight is chosen as a quantity indicator; then the water volume per piece of the product or number of pieces is measured. If the WF of processes is measured, it is usually expressed as water volume per unit of time. When this unit is divided by the units of products measured during that time, then it can also be expressed as water volume per unit of product [14].

II. WATER FOOTPRINT ASSESSMENT (WFA)

WAF helps to feed the discussions in both public and private sectors on environmentally sustainable, economical efficient and socially equitable water use, allocation, helps to assess environmental, social and economic impacts of water use and can inform a broad range of strategic actions and policies from environmental, social and economic perspectives. WFA consist of four phases (1) Setting goals and scope, (2) Water footprint accounting, (3) Water footprint sustainability assessment, (4) Water footprint response formulation [15]. There are different methodologies and valuable tools for industrial water footprint. The International Organization for Standardization has developed frame work for calculating the water footprint, by following the guide lines of ISO 14046:2014 WAF can be conducted based on a life cycle assessment (according to ISO 14044) that identifies potential environmental impacts related to water [16]. Different methodologies and tools used for water accounting to calculate water footprint. There are two methodologies available for water footprint i.e. AWARE and Pfister et al. approach. These methodologies based on the water gap model. Pfister approach; utilized the Water Scarcity index (WSI) as characterization factor for water consumption use in life cycle impact assessment to measure potential environmental damage of water use for human health, ecosystem quality and resource. This approach considers both mid-point and endpoint characterization factor for assessing the environmental impacts of fresh water consumption [17].
